Neuroprotective role of galectin-1 in central nervous system pathophysiology

Galectins are a family of endogenous β-glycan-binding proteins that play an important role in the modulation of inflammation-associated with neurodegeneration as seen in various neurological disorders such as dementia, multiple sclerosis (MS), Alzheimer’s disease (AD) (Chen et al., 2014). Members of the galectin family specifically galectin-1, -3 and -9 are involved in neuromodulation via cytokine production contributing to central nervous system (CNS) pathology and/or neuro-preservation. Galectins are expressed by activated microglia/infiltrating macrophages and astrocytes and recently we have shown that they are also expressed by brain microvascular endothelial cells that constitute the blood-brain barrier (BBB) (Parikh et al., 2015). Several studies have shown that galectins are important modulators participating in homeostasis of the CNS and neuroinflammation. Galectins contribute to CNS pathophysiology by either controlling the inflammatory response or by remodeling damaged CNS tissues. Since galectins are pro-inflammatory mediators in the CNS, either modulation of their expression or activity could be a sound therapeutic strategy for a variety of neurological disorders mentioned above.

HIV-1 targets the CNS early in infection, specifically in subcortical brain regions resulting in cognitive disturbances linked both to viral activity and inflammatory response leading to the neuronal apoptosis causing a spectrum of HIV-associated neurocognitive disorders (HAND). Long-term HIV replication in the brain occurs in astrocytes and microglia, allowing the sequestered virus to compromise neuronal function. Galectin-1 promotes HIV-1 binding to susceptible CD4+ cells enhancing viral infection suggesting that CD4 is one of the host ligand of galectin-1 (Mercier et al., 2008; St-Pierre et al., 2011). It is believed that galectin-1 facilitates HIV-1 infection through direct cross-linking of HIV gp120 and host cell surface CD4 receptor. Additionally, galectin-1 promotes infection of HIV-1 X4, X4R5, and R5 variants in susceptible cells as well. HIV-1 susceptible CNS cells may have affinity for galectin-1 due to the presence of glycosylated protein receptors thus responding to the immune reactions and inflammatory events mediated by galectin-1. Microglial cells are the resident macrophages of the brain and act as the first line of defense in the CNS microglia constitute the lesser portion of the total glial cell population within the brain and are found in a resting state in the healthy CNS. Under pathological conditions microglia get activated and undergo morphological changes in addition to inducing expression of proinflammatory cytokines like interleukin (IL)-1β, IL-6, IL-8, tumor necrosis factor-α (TNF-α), chemokines, reactive oxygen and nitrogen species, all of which cause neuronal damage (Kettenmann et al., 2011). A variety of microglia receptors are involved in triggering an inflammatory response, specifically via receptor for advanced glycosylation endproducts (RAGE), complement receptor C5aR and certain toll like receptors (TLRs). C5a is a highly proinflammatory molecule generated in the process of complement activation. CD88 is a receptor for C5a expressed on the surface of innate immune cells, including microglia. The interaction between C5a and CD88 leads to the production of inflammatory cytokines and reactive oxygen species. (Woodruff et al., 2010). Micrornal expression of TLR-2, -4 and -9, have been associated with microglial activation and neurotoxicity highlighting their role in neuropathology (Lehnardt, 2010). It will be interesting to investigate if galectin-1 modulates the expression of RAGE, C5aR or TLRs thereby altering inflammatory response. Our current studies are focused on exploring the mechanisms of galectin-1 action.

In the context of HAND, activation of TLRs on microglial cells by morphine and HIV protein Tat has been shown to contribute to the increased neuropathophysiology (Dutta et al., 2012). HIV-1 Tat or gp120 alone and in combination with morphine modulate the expression of TLR-2, -4 and -9 in astrocytes resulting in the expression of inflammatory cytokines (El-hage et al., 2011). Although the role of these microglial receptors in the neuroinflammatory response is established, limited information is available on the role of endogenous ligands such as galectins that may trigger activation of TLRs, C5aR or RAGE. A recent report showed galectin-3-dependent-TLR4 activation could contribute to sustained microglia activation, prolonging the inflammatory response in the brain (Burguillos et al., 2015). Activated microglia contribute to CNS pathology or repair, depending on the prevalent microenvironment and their mode of activation, typically activated microglia are associated with neurodegeneration. When endogenous galectin-1 is absent, classical microglial activation occurs, concurrent with an increase in demyelination, axonal loss and a reduction in endogenous synaptic within CNS inflected by HIV infection in CHME-5 cells (generously donated by Dr. J. Karn, CWRU, Cleveland, OH). CHME-5 cell line was created by transfecting human fetal microglia with the large T antigen of the simian virus 40 and both CHME-5/CHM5-HIV cells are maintained in Dulbecco’s minimal essential medium, high glucose (DMEM H) supplemented with 5% FBS and 1% penicillin/streptomycin. Treatment of CHME-5 and CHME-5/HIV with LPS (30 ng/ml) stimulated the production of inflammatory cytokines resulting in an increase in oxidative stress as measured by reactive oxygen species (ROS) production. ROS includes superoxide (O2-), hydrogen peroxide (H2O2) and hydroxyl radical (OH), which under physiological conditions are generated at low levels and play important roles in signaling and metabolic pathways. Increased oxidative stress causes the generation of ROS, which are potentially toxic for cells further contributing to neuroinflammation. We observed increased lบา с expression in HIV transfacted CHME-5/HIV microglia as compared to untransfected CHME-5 cells indicative of increased microglial activation in HIV infected cells (Figure 1A, B). We hypothesize that galectin-1 would reduce neuroinflammation in both human microglia cell line CHME-5 and CHME-5/HIV. Our results (Figure 1C, D) showed that treatment with galectin-1 (1 µM) decreased microglial activation in both CHME-5 and CHME-5/HIV cells. Histograms shown in Figure 1E, F show the Image J quantitation of fluorescence signal intensity in pixel units of representative fluorescent images shown in Figure 1A, B and Figure 1C, D respectively. Treatment of microglia with pro-inflammatory cytokines such as galectin-1 (1 µM) reduced oxidative stress by ~25% (P < 0.05) in CHME5/HIV cells when compared to the LPS treated cells (Figure 2). Our data suggests that galectin-1
Figure 1 Immunofluorescence staining using Iba-1 antibody.
Primary antibody is a mouse monoclonal and fluorescence labeled secondary antibody (yellow) (Alexa Fluor 647 rabbit anti-mouse). Nuclear stain DAPI (blue). The fluorescent signal intensity analyzed using Image J software Imaging done using EVOS FL Cell Imaging System. Iba-1 is a microglial marker. Increased Iba-1 expression in CHME-5/HIV indicating microglial activation in the HIV transfected microglia. DAPI; 4’-diamidino-2’-phenylindole; Iba-1; ionized calcium-binding adapter molecule 1.

Figure 2 ROS/RNS assay (Cell Biolabs kit).
The assay employs a proprietary quenched fluorogenic probe DiOxyQ (DCFH-Di-OxyQ), which is a specific ROS/RNS probe. Briefly, the DCFH-DiOxyQ probe is first primed with a quench removal reagent, and subsequently stabilized in the highly reactive DCFH form. In this reactive state, ROS and RNS species react with DCFH, which is rapidly oxidized to the highly fluorescent DCF. The amount of DCF expressed as the fluorescence intensity is proportional to the total ROS/RNS levels within the sample. Treatment of CHME-5/HIV with LPS resulted in 60 % increase (P < 0.01) in oxidative stress in CHME-5 and a 26% increase (P < 0.05) in CHME5/HIV respectively compared to the untreated control. Treatment of microglia with galectin-1 (1 mM) reduced oxidative stress by ~25% (P < 0.05) in CHME5 and by ~60% in CHME-5/HIV as compared to the LPS treated cells. DCF: 2’7’-dichlorofluorescin; ROS/RNS: reactive oxygen species/reactive nitrogen species.
